

TrustFlow AI v2

AI-powered escrow that lets strangers buy and sell safely — money is held until the buyer confirms, an AI flags scams before anyone ships, and an AI settles disputes. Built on Wema's own ALAT rails.

WHAT CHANGED SINCE VERSION 1

- **The design is finished.** All the app screens are done. The one design task still left is to send the arrow-linked screens into our Figma file — that's it.
- **Deji now moves to the front end.** Instead of designing, Deji now builds those finished screens as real, working code (the part users tap and see) — and only that.
- **Jerry and H2O share the back end equally.** They build the engine behind the screens together — the payments, the escrow, the AI, and the database — splitting the work between them, not one doing it all.
- **Everything else is the same.** Same idea, same plan to win, still three people, still a one-week sprint.

THE IDEA, IN PLAIN WORDS

Buy and sell from strangers without getting scammed.

Right now, if you buy something on WhatsApp or Instagram, you either pay first and pray the seller ships, or the seller ships first and prays you pay. Somebody always risks getting cheated. TrustFlow removes that risk by holding the money safely in the middle until both sides are happy.

1 • Secure Money is held safe The buyer pays into a safe holding wallet (escrow). The seller can see the money is there, so they ship with confidence.	2 • Score AI checks the seller The AI reads the chat and the seller's history and gives a Trust Score (0–100) that warns the buyer if it smells like a scam.	3 • Release Buyer confirms, seller paid When the buyer gets the item and is happy, the held money is released to the seller instantly.	4 • Resolve AI settles fights If the two disagree, the AI looks at the evidence from both sides and decides fairly: pay the seller, refund the buyer, or split it.
--	--	--	--

The same app, but running on Wema's own payment system.

This idea was first written for a different competition (Squad's) and used Squad's payment tools. For Wema, we swap those out for Wema's own ALAT tools — because a Wema-owned bank would never reward an app built on a rival's system. Here is exactly what swaps for what.

What it does	Old (Squad)	New (ALAT)
Holds the money	Squad Virtual Account	ALAT Wallet Services — holds funds like a full bank account
Buyer pays in	Squad checkout	ALATPay (card, USSD, transfer)
Confirms payment	Squad webhook	ALATPay alert → marks the deal "funded"
Pays the seller	Squad Transfer	ALAT Merchant Payout — instant payout

Getting live ALAT access needs sign-off from a bank contact, which takes time — so for the demo we use ALAT's free test mode and mention live access as the next step. Start this request on Day 1, it's the slowest thing to arrive.

WHY A BANK WILL LOVE IT

Held money sits inside Wema — and that's the whole point.

What the judges care about	Our answer, plainly
More money in the bank	Every deal parks cash in a Wema wallet until it's released. That's real money sitting inside Wema — exactly what a bank chasing growth wants.
Banking more people	It brings the huge WhatsApp / Instagram / campus trading crowd — people with no protection today — into Wema's system.
Real use of AI	Three genuine AI features (scam score, scam detection, dispute judge), not AI sprinkled on for show.
A feature they could ship	It's designed to look and feel like it already lives inside the ALAT app — so it reads as something Wema could launch, not a random side project.

Who does what in version 2.

Team lead Jerry Back end Shares the engine with H2O. Owns the ALAT escrow and payments side (holding money, taking payment, paying out, refunds) and keeps the team on schedule. Same job level as H2O — they split the back end.	H2O Back end Shares the engine with Jerry. Owns the AI side (the Trust Score, the scam detector, the dispute judge) plus the deal logic and data. Equal partner on the back end — not a smaller role.	Deji Front end Turns the finished designs into a real, working app that people can tap through, and connects each screen to the back end. Front end only — design is done, just needs pushing to Figma.
---	--	--

DEJI'S MOVE • FROM DESIGNING TO BUILDING

The design is done. Now you build it for real.

Your first job takes an hour, not a day: **push the finished, arrow-linked screens into the Figma file**. After that, you're a front-end developer for the rest of the sprint — taking each design and making it a real screen in code that actually works when you tap it.

The simple rule: build each screen as a real page, then hand it to Jerry or H2O to connect to the engine — or connect it yourself where it's easy. Start with the screens the judges see most: the Dashboard and the Trust Score result. Because the design is already decided, you never have to stop and wonder how something should look — you just build what's in front of you.

One week: design pushed to Figma, app built, submitted.

No Wema deadline is public and the campus tour has already started, so we treat it as urgent. Each task is tagged with who owns it.

Day 1 Set up & first screens

The app opens and people can log in

- Register the team on the Wema portal.** Hackathon track, Financial Inclusion, Lagos centre — if not already done. All
- Push the finished designs into Figma.** The arrow-linked screens. Deji's last design task — do it first, it's quick. Deji
- Set up the code project + database.** Next.js and Supabase with the four data tables. Also request ALAT test access — the slowest thing to arrive. Jerry
- Set up login + the AI tools and first prompts.** Email/Google sign-in, and get the Trust Score and scam-detector prompts ready to plug in. H20
- Build the Landing and Login screens in code.** Straight from the finished designs. The first thing anyone sees. Deji

Day 2 Money goes into escrow

A buyer can pay and the app knows it

- Build the escrow wallet + take payment.** Buyer pays into a safe ALAT wallet; the app marks the deal "funded" when the cash truly lands. Jerry
- Build the expiring account number.** A one-time account that dies after ~10 min — this kills fake payment receipts. H20
- Build the "create a deal" logic + save it.** Amount, item, seller, and the pasted chat all get stored. H20
- Build the Dashboard and New Escrow screens.** In code, connected to the deal logic so they show real data. Deji

Day 3 The AI brain

Paste a scam chat, get a warning score

- Build the Trust Score + scam detector.** Reads the chat and history, returns a 0–100 score and the reasons behind it. H20
- Add two demo sellers.** One clearly safe (score 87), one clearly dodgy (score 23) so the demo always works. Jerry
- Build the Trust Score screen (both looks).** The calm green "safe" version and the scary red "risky" version, showing real AI answers. Deji
- Build the Fund Escrow / expiring-account screen.** Shows the account number and counts down; flips to "money locked" on its own. Deji

Day 4 Payout & handover locks

Money reaches the seller safely

- Build "confirm received" → pay the seller.** Buyer taps confirm, ALAT pays the seller's bank instantly (after checking the account). Jerry
- Build the handover code + auto-release timer.** Buyer's secret code releases the money; if the buyer goes silent, it auto-releases fairly. H20
- Build the dispute judge (AI).** Weighs both sides and recommends: pay, refund, or split. H20
- Build the Timeline, Code and Proof screens.** Shows where the money is, the handover code, and the live photo/video proof. Deji

Finish the full dispute flow. Open dispute → both sides give evidence → AI decides → money moves.

H20

Build refunds + the receipt. Full or partial refund back to the buyer, and a shareable receipt at every step.

Jerry

Build the Dispute, Receipt, Profile and Seller sign-up screens. Including the ID check every seller must pass before they can be paid.

Deji

Day 6 Join it all up & polish

It survives a stranger tapping around

Connect every screen to the real engine + first full run-through. Do a whole deal end to end. Expect breakage — that's what today is for.

A11

Make it work on phones + handle mistakes. Every screen at phone size; friendly loading, empty and error messages.

Deji

Fill it with believable demo data. A few finished deals, one live, one in dispute — so it looks real, not empty.

Jerry

Test the AI for wrong answers. Run honest chats through it, count mistakes, know the number before a judge asks.

H20

Day 7 Ship & pitch

Submitted, rehearsed, ready

Put the app online. A live link that works on a phone and on hotspot, not just on a laptop at home.

Deji

Final back-end check + tidy the code + write the README. Screenshots, a short explanation, and how to run it. Judges do look.

Jerry

Record a backup demo video. A clean recording saved offline, in case the venue wifi fails.

H20

Build the deck, write the 4-minute pitch, practise 3 times, submit. Open with a real "I got scammed online" story; show the score drop live.

A11

The app is built so neither side can trick the other.

The trick someone might try	How the app blocks it
Fake payment receipt	We never trust screenshots. The buyer pays into a one-time account that expires in ~10 minutes, and the deal only becomes "funded" when the money truly lands. A photoshopped receipt does nothing.
Buyer lies "I never got it"	The buyer holds a secret handover code. The seller is only paid once that code is used — so the buyer can't claim it never arrived if their own code released the money.
Buyer goes silent to trap the money	After delivery is proven, a timer runs. If the buyer neither confirms nor disputes, the money auto-releases to the seller. Nobody can freeze it forever.
Seller sends fake goods	The buyer records an unboxing with the app's own camera (no gallery uploads), so the AI dispute judge has real, un-fakeable evidence.
Banned scammer comes back	Every seller must verify their real identity (BVN/NIN) before they can be paid, and payouts only go to a matching bank account. A banned identity can't just make a new profile.

Good to know: a buyer does **not** need to be a Wema customer — they pay in from any bank. But every **seller** must be verified. That keeps it open to everyone while still safe.

Day 1, first things first: register, push the designs to Figma, and start the ALAT test-access request.

Those three unlock everything else and can't be rushed at the end. After Day 7 we're only polishing and rehearsing — watching the portal for the Lagos pitch date. Registration: hackaholics.wemabank.com/hackathon
